The high dimensional low sample and one-sidedness nature of microarray data poses a lot of difficulties for a computer based diagnostic system. Hence careful analysis of microarray data has a significant impact on identification of diseases. This book introduces multistage mutual information (MSMI) for gene selection that computes Mutual Information (MI), initially using all the samples and based on the classification performance produced by Artificial Neural Network (ANN), MI is repeatedly calculated using only the unclassified samples until there is no improvement in the classification accuracy. A Fuzzy-Rough set based f -Information (FR f -I) approach is discussed to avoid discretization during gene selection that generates Fuzzy Equivalence Class (FEC) for every gene and then constructs a Fuzzy Equivalence Partition Matrix for estimating the Gene-Class relevance and Gene-Gene redundancy.

Even though the genes selected by the FR f -I method are highly informative, the classification results produced by ANN are hard to interpret as they focus only on the classification accuracy. Expert Systems based on Fuzzy Logic (FL) are highly required in medical diagnosis because of its ability to incorporate human expert knowledge in decision making. In this book, the issue of knowledge acquisition is formulated as an optimization problem and a novel Genetic Swarm Algorithm (GSA) is introduced for optimal generation of rule set and tuning of membership function. Even though the results produced by the GSA approach produces a well-informed classifier model, the knowledge produced by it is difficult

to understand. A hybrid Ant Bee Algorithm (ABA) is discussed to address this interpretability-accuracy tradeoff.
